Moving inventory intelligence beyond reactive ERP reporting, in 12 weeks

A premier automotive manufacturer engaged Sthiros to architect a Data Intelligence Platform, transforming latent SAP S/4HANA records into active enterprise intelligence.

Client	Service	Sector	Geography
A Premier Automotive Manufacturer	**Data Intelligence Platform, Inventory & Master Data**	**Automotive Manufacturing**	**India**

The Challenge:

When standard ERP reporting can't steer the supply chain

As this manufacturer scaled, standard transactional reporting within SAP S/4HANA proved insufficient for strategic steering. A fragmented data landscape meant procurement and production couldn't align on a single version of the truth, and any attempt at advanced simulation or stock-out modelling was compromised by data silos.

Static Inventory Assumptions

Static stock assumptions induced production instability through alternating cycles of material shortages and costly overstock.

Master Data Fragmentation

A fragmented data landscape compromised operational controls and introduced systemic risk into enterprise-level analytics.

Reactive Exception Handling

With no early warning systems, supply variability forced high-pressure, manual responses instead of planned action.

Vendor Data Inconsistencies

Inconsistent vendor master data degraded data integrity and placed disproportionate pressure on working capital.

The Solution:

A five-layer governed pipeline, on-premise by design

Sthiros architected a secure, on-premise Data Intelligence Platform, isolating analytical workload from the core transactional environment to protect ERP stability while enabling high-performance processing.

Master data was remediated alongside the build, vendor payment terms standardised, duplicate vendor codes merged, and redundant part codes cleaned up, restoring trust in the numbers the new engine would run on. The shift was from static stock assumptions, which drove alternating cycles of shortage and excess, to dynamic, data-driven visibility that responds to real supply variability.

The Methodology

1 Data Ingestion

Secure extraction of transactional and master data, inventory, procurement, and planning, directly from the SAP S/4HANA source.

2 Processing and Standardisation

A cleansing and enrichment layer enforcing consistency across disparate business units.

3 Semantic Modelling

A governed analytical layer built as the single version of truth for all inventory decision-making.

4 Alert Engine

A rule-based logic layer continuously interrogating data patterns to identify emerging risks.

5 Dashboarding

User-centric planning views translating complex analytical outputs into actionable operational tasks.

What This Means

Replace static rules with reality.

Clean data first, alerts second.

Decisions that outlast the planner.

Outcomes

12 Weeks

Full deployment, diagnostic to live platform

From root-cause diagnosis through to a live, governed Data Intelligence Platform.

5-Layer

Governed pipeline architecture

From SAP ingestion through semantic modelling to dashboarding, replacing fragmented reporting with one architecture.

Early Warning

Stock-out risk visibility

Shortage and excess conditions detected from historical usage and supplier lead-time behaviour, before they hit production.

Action-Tracked

Governance model

Every alert accepted, rejected, or deferred by planners, creating an audit trail and codifying institutional knowledge.
